

Functions

- You may be very familiar with the mathematical concept of a **function**

$$z = f(x, y)$$

f is a function that operates on the inputs x and y . The output of the function is z .

However, programming functions are much more generalized and versatile than this mathematical definition.

•How to define
a function?

Preview Exercise:

Which keyword is used to define function?

- ☐ A Fun
- ☐ B Define
- ☒ C Def
- ☐ D Function

提交

Functions

- Function is **a block of code** which only **runs** when it is **called**
- Reusable pieces/chunks of code
- Function characteristics:
 - has a **name**
 - has **a colon (:) to mark the end of the function header**
 - has **parameters(arguments)** (0 or more)
 - has a **docstring** (optional) : comment document
 - has a **body**
 - **Possibly returns** something

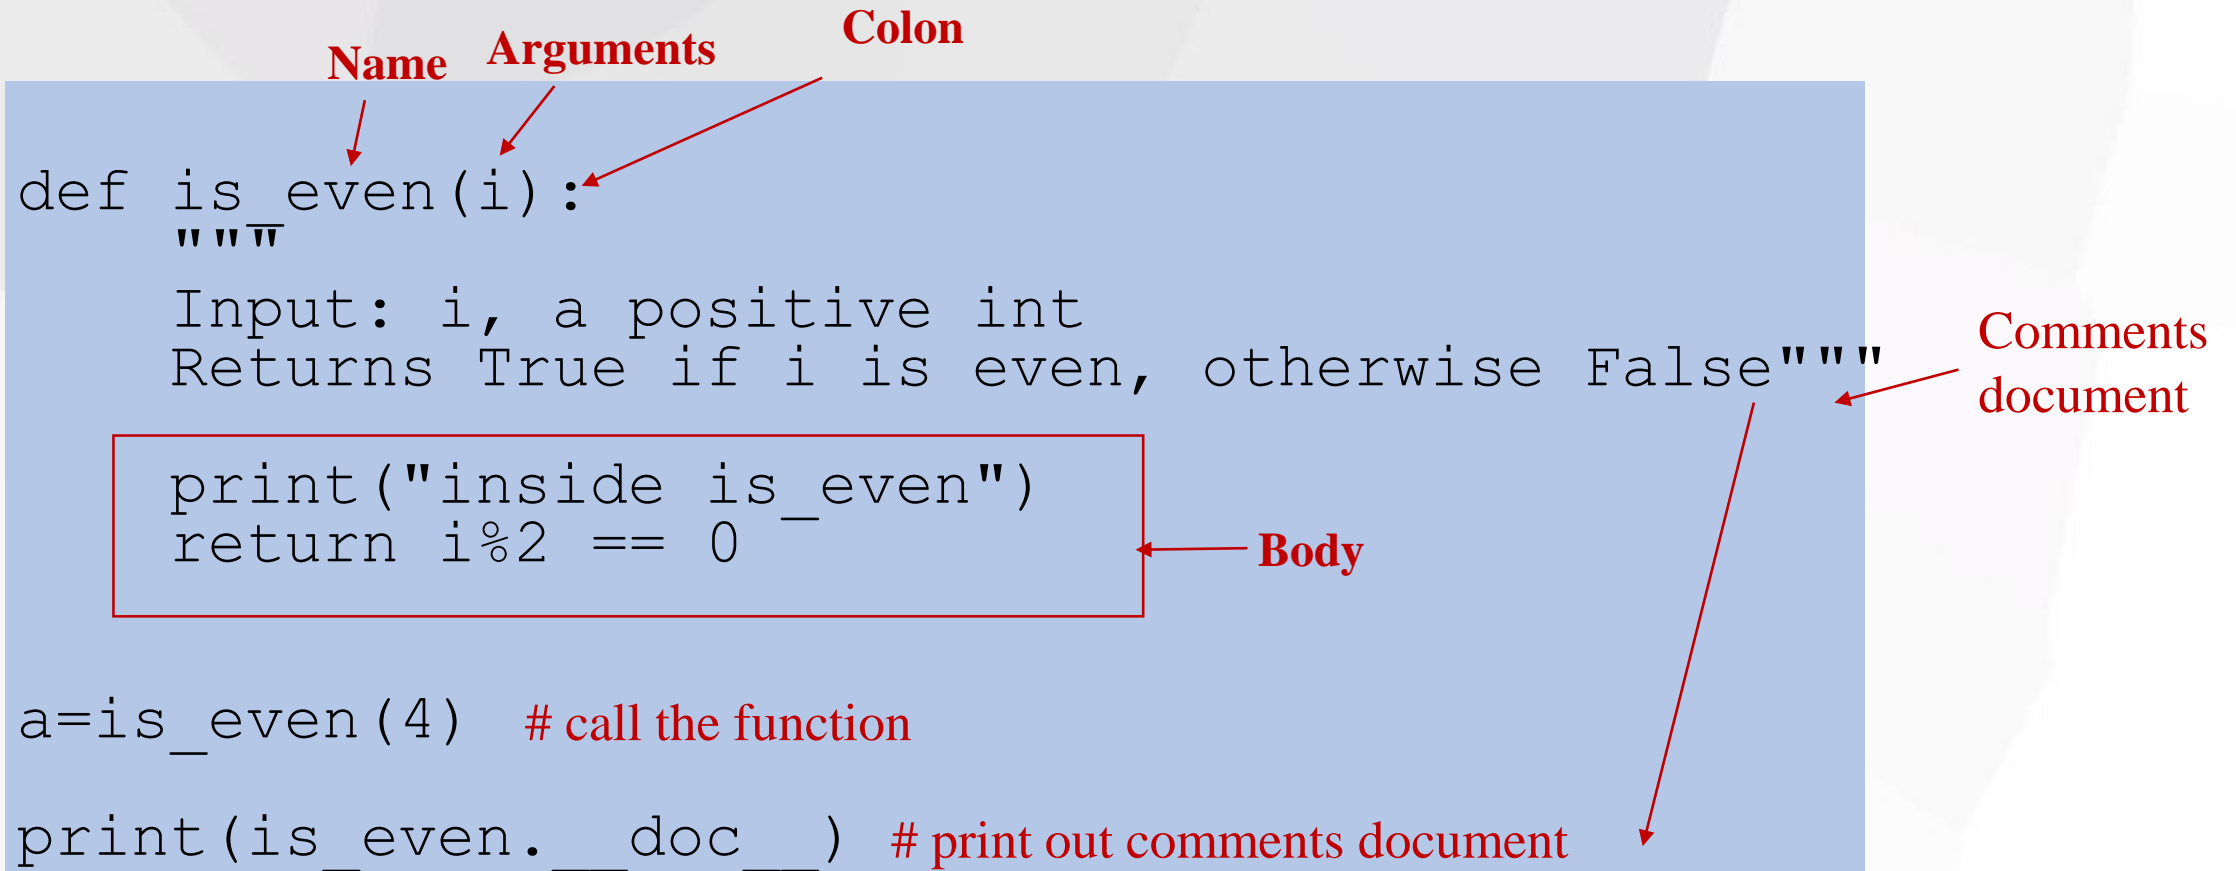

Functions

- A function is created with the **def** keyword. The statements in the block of the function must be **indented**.

```
def function_name(args):  
    statements  
    return values
```

- The **def** keyword is followed by the function name with round brackets enclosing the arguments and a **colon**.
- The **return** keyword is used to specify a list of values to be returned.

How to Write a Function

The diagram illustrates the components of a Python function definition. Red arrows point from labels to specific parts of the code:

- Name**: Points to `is_even` in `def is_even(i):`
- Arguments**: Points to `(i)` in `def is_even(i):`
- Colon**: Points to the colon `:` in `def is_even(i):`
- Comments document**: Points to the docstring `"""
Input: i, a positive int
Returns True if i is even, otherwise False"""`
- Body**: Points to the function body `print("inside is_even")
return i%2 == 0`, which is enclosed in a red box.

```
def is_even(i):  
    """  
    Input: i, a positive int  
    Returns True if i is even, otherwise False"""  
    print("inside is_even")  
    return i%2 == 0  
  
a=is_even(4) # call the function  
print(is_even.__doc__) # print out comments document
```

If No Return Statement

```
def is_even( i ):  
    """  
    Input: i, a positive  
    int    Does not return  
    anything    """  
    i%2 == 0  
a=is_even(4)
```

← **Body**

- Python returns the value **None**, if no return given

Functions: Name

- The rules for naming a function are a lot like rules for naming a variable:
 - They must start with **a letter or an underscore**:
 - They can have **numbers**.
 - They can be **any length** , but keep them short.
 - They should **uniquely** identify the function
 - They **can't be the same as a Python keyword**.
 - They can have the same name as an existing function (including a built-in), but avoid this for now.

def this_is_my_function(): **def** _f3(x):
